- ▶ Suppose we have:
 - ▶ Some response variable, Y
 - ▶ Some covariate factor, X , with levels $i = 1, 2, \dots, r$ and n_i observations at level i .
- ▶ The **one-way ANOVA model**, sometimes called the one-way normal model, is:

$$Y_{ij} = \mu_i + \varepsilon_{ij}$$

where:

- ▶ The ε_{ij} 's are iid $N(0, \sigma^2)$
- ▶ μ_i is the true mean response at level i of the factor.
- ▶ $j = 1, 2, \dots, n_i$.

obs. for level i has a mean μ_i

variance for these r populations are the same.

The one-way ANOVA model

$$Y_{ij} = \mu_i + \varepsilon_{ij}$$

$\mu_i - \mu_j$

Inference

Confidence interval
for linear
combination of
means

Example: concrete

- Compressive strengths of 8 different formulas of concrete:

- But the order of the numbers given to the formulas is meaningless. It wouldn't make sense to do a simple linear regression of strength on formula.

Example: concrete

- Instead of:

$$\underline{Y_i = \beta_0 + \beta_1 X_i + \varepsilon_i}$$

with Y_i as strength and X_i as the formula index, we use:

$$\underline{Y_{ij} = \mu_i + \varepsilon_{ij}}$$

where:

- i is the formula index, $i = 1, 2, \dots, 8$
- j is the index of a specimen within the formula i group.

Example: springs

- Spring constants of three types of steel springs:

Empirical Spring Constants

Type 1 Springs	Type 2 Springs	Type 3 Springs
1.99, 2.06, 1.99	2.85, 2.74, 2.74	2.10, 2.01, 1.93
1.94, 2.05, 1.88	2.63, 2.74, 2.80	2.02, 2.10, 2.05
2.30		
$n_1 = 7$	$n_2 = 6$	$n_3 = 6$

The one-way
ANOVA model

Residuals and
fitted values

Variance
estimation

Standardized
residuals

Inference

Confidence interval
for linear
combination of
means

Example: springs

- ▶ Doesn't make sense to regress exponential spring constant on spring type.
- ▶ Instead, we apply:

$$Y_{ij} = \mu_i + \varepsilon_{ij}$$

where:

- ▶ Y_{ij} is the exponential spring constant of spring type i spring number j .
- ▶ μ_i is the true mean exponential spring constant of type i . *spring type.*
- ▶ i is the ~~formula~~ index, $i = 1, 2, \dots, 3$.
- ▶ j is the index of a specimen within the formula i group.

Confidence interval
for linear
combination of
means

Fitted values

- ▶ Similarly to before, \hat{y}_{ij} is the fitted value corresponding to y_{ij} . It represents an estimate of the true mean response at factor level i and sample unit j . $E(y_{ij}) = \mu_i$.

- ▶ We treat all sample units equally, letting;

$$\hat{y}_{ij} = \hat{\mu}_i = \bar{y}_{i.} = \frac{1}{n_i} \sum_{j=1}^{n_i} y_{ij}$$

the average of all the responses at factor level i .

- ▶ We get $\hat{\mu}_i = \bar{y}_{i.}$ by minimizing the loss function:

$$S(\mu_1, \mu_2, \dots, \mu_r) = \sum_{ij} (y_{ij} - \mu_i)^2$$

over all the choices of $\mu_1, \mu_2, \dots, \mu_r$, selecting $\bar{y}_{i.}$ to estimate μ_i .

- ▶ The residuals e_{ij} are then:

$$e_{ij} = y_{ij} - \bar{y}_{i.}$$

Example: concrete

Example Computations of Residuals for the Concrete Strength Study

Specimen	i , Concrete Formula	y_{ij} , Compressive Strength (psi)	$\hat{y}_{ij} = \bar{y}_i$, Fitted Value	e_{ij} , Residual

Variance estimation

- ▶ We can compute a sample variance for each factor level:

$$s_i^2 = \frac{1}{n_i - 1} \sum_j (y_{ij} - \bar{y}_{ij})^2$$

Handwritten notes: A blue arrow points from \bar{y}_i to \bar{y}_{ij} . A blue line is drawn under the entire equation.

- ▶ And we can compute a pooled sample variance:

$$s_P^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2 + \cdots + (n_r - 1)s_r^2}{(n_1 - 1) + (n_2 - 1) + \cdots + (n_r - 1)}$$

Handwritten notes: Blue lines are drawn under each $(n_i - 1)$ term in both the numerator and denominator.

Handwritten note: $r^{n-r} \leftarrow \# \text{ of groups/levels.}$

Handwritten note: $n_1 + n_2 + \cdots + n_r$ total sample size.

- ▶ The pooled sample standard deviation is just $s_P = \sqrt{s_P^2}$

Variance estimation

- If $n = \sum_i n_i$, then:

$$s_P^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2 + \cdots + (n_r - 1)s_r^2}{(n_1 - 1) + (n_2 - 1) + \cdots + (n_r - 1)}$$

$$= \frac{(n_1 - 1) \left(\frac{1}{n_1 - 1} \right) \sum_j (y_{1j} - \bar{y}_1)^2 + \cdots + (n_r - 1) \left(\frac{1}{n_r - 1} \right) \sum_j (y_{rj} - \bar{y}_r)^2}{n - r}$$

$$= \frac{1}{n - r} \sum_{ij} (y_{ij} - \bar{y}_i)^2$$

$$= \frac{1}{n - r} \sum_{ij} e_{ij}^2$$

- As it turns out,

$$E(s_P^2) = \sigma^2$$

$$\frac{n - r}{\sigma^2} s_P^2 \sim \chi_{n-r}^2$$

- A $1 - \alpha$ confidence interval for σ^2 is of the form:

$$\left(\frac{n - r}{\chi_{n-r, 1-\alpha/2}^2} s_P^2, \frac{n - r}{\chi_{n-r, \alpha/2}^2} s_P^2 \right)$$

$$P \left(\chi_{n-r, \alpha/2}^2 \leq \frac{n-r}{\sigma^2} s_P^2 \leq \chi_{n-r, 1-\alpha/2}^2 \right)$$

$$= 1 - \alpha \cdot \left[\frac{n-r}{\chi_{n-r, 1-\alpha/2}^2} s_P^2 \leq \sigma^2 \leq \frac{n-r}{\chi_{n-r, \alpha/2}^2} s_P^2 \right]$$

Yifan Zhu

The one-way
ANOVA model

Residuals and
fitted values

Variance
estimation

Standardized
residuals

Inference

Confidence interval
for linear
combination of
means

Example: concrete

$$\alpha = 1 - 0.9 = 0.1$$

$$\chi_{n-r, 1-\alpha/2}^2$$

$$\chi_{n-r, \alpha/2}^2$$

► $n = 24$, $r = 8$, $n - r = 16$.

► $\chi_{16, 0.95}^2 = 26.296$, $\chi_{16, 0.05}^2 = 7.962$

► Hence, a 90% 2-sided confidence interval for σ^2 is:

$$\left(\frac{16 \cdot 581.6^2}{26.296}, \frac{16 \cdot 581.6^2}{7.962} \right)$$

$$= (205816, 679745.9)$$

and you can make a 90% confidence interval for σ by transforming the endpoints of the confidence interval for σ^2 :

$$(\sqrt{205816}, \sqrt{679745.9}) = (453.7, 824.5)$$

- We're 90% confident that the true overall standard deviation of compressive strength of the concrete within factor levels is between 453.7 psi and 824.5 psi.

- ▶ Just as before, even though $\varepsilon_{ij} \sim \text{iid } N(0, \sigma^2)$, the ε_{ij} 's don't have constant variance.
- ▶ The **standardized residuals** for the one-way ANOVA model are of the form:

$$e_{ij}^* = \frac{e_{ij}}{\text{SP} \sqrt{\frac{n_i - 1}{n_i}}} = \sigma^2 \cdot \frac{n_i - 1}{n_i}$$

Handwritten notes: $\text{Var}(e_{ij})$ and $\sigma^2 \cdot \frac{n_i - 1}{n_i}$ are written in red above the denominator and the right-hand side of the equation, respectively.

which are approximately $N(0, 1)$.

Inference for the one-way ANOVA model

1. $H_0 : \mu_1 = \mu_2 = \dots = \mu_r$, $H_a : \text{not all the } \mu_i\text{'s are equal.}$
2. α is some sensible value.
3. The test statistic is:

$$F = \frac{MSR}{MSE} = \frac{SSR/(r-1)}{SSE/(n-r)}$$

► Here,

- n is the number of observations.
- r is the number of levels of the covariate.

$$\text{► } SSR = \sum_{ij} (\hat{y}_{ij} - \bar{y}_{..})^2 = \sum_{ij} (\bar{y}_{i.} - \bar{y}_{..})^2$$

$$\text{► } SSE = \sum_{ij} (y_{ij} - \hat{y}_{ij})^2 = \sum_{ij} (y_{ij} - \bar{y}_{i.})^2$$

- Assume H_0 is true, the model is valid, and the ε_{ij} 's are iid $N(0, \sigma^2)$
- Then, $F \sim F_{r-1, n-r}$.
- Reject H_0 if $F > F_{r-1, n-r, 1-\alpha}$

4. Compute the observed F using data. To do that, we can construct the ANOVA table:

The one-way
ANOVA model

Residuals and
fitted values

Variance
estimation

Standardized
residuals

Inference

Confidence interval
for linear
combination of
means

Source	SS	df	MS	F
<u>Covariate</u>	<u>SSR</u>	<u>$r - 1$</u>	<u>$SSR / (r - 1)$</u>	<u>MSR / MSE</u>
<u>Error</u>	<u>SSE</u>	<u>$n - r$</u>	<u>$SSE / (n - r)$</u>	

5. If $observedF$ > $F_{r-1, n-r, 1-\alpha}$, reject H_0 ; or we can compute the p-value:

$$P(F_{r-1, n-r} > observedF)$$

If the p-value is small, we reject H_0 .

6. Conclusion in layman's term.

Example: concrete

1. $H_0 : \mu_1 = \mu_2 = \cdots = \mu_8$, $H_a : \text{not all the } \mu_i\text{'s are equal.}$
2. $\alpha = 0.05$
3. The test statistic is:

$$F = \frac{MSR}{MSE} = \frac{SSR / \underline{(r-1)}}{\underline{SSE / (n-r)}} = \frac{SSR / \textcircled{7}}{SSE / 16}$$

- ▶ Assume H_0 is true, the model is valid, and the ε_{ij} 's are iid $N(0, \sigma^2)$
- ▶ Then, $F \sim F_{r-1, n-r}$ = $F_{7,16}$
- ▶ Reject H_0 if $F > F_{r-1, n-r, 1-\alpha}$ = $F_{7,16,0.95}$ = 2.66

Inference

Confidence interval
for linear
combination of
means

Example: concrete

$$\underline{SSR = SST - SSE}$$

4. We start by calculating SST, s_p^2 , and SSE:

$$\begin{aligned} & (\underline{5,800} - \underline{3,693.6})^2 + (4,598 - 3,693.6)^2 + (6,508 - 3,693.6)^2 \\ & + \cdots + (2,631 - 3,693.6)^2 + (2,490 - 3,693.6)^2 \\ & = \underline{52,772,190 \text{ (psi)}^2} \end{aligned} \quad s_p^2 = \frac{SSE}{n-r}$$

$$\underline{s_p^2} = \underline{338,213.1 \text{ (psi)}^2} \text{ and } n - r = 16, \text{ so}$$

$$\underline{SSE} = (n - r) \underline{s_p^2} = \underline{5,411,410 \text{ (psi)}^2}$$

Lastly, we calculate SSR:

$$\sum_{i=1}^r n_i (\bar{y}_i - \bar{y})^2 = \underline{47,360,780} \quad \begin{matrix} \text{SST} - \text{SSE} \\ \downarrow \end{matrix}$$

Example: concrete

- ▶ When we have multiple samples with means $\mu_1, \mu_2, \dots, \mu_r$, we want to compare these means
- ▶ There are many possibilities: μ_1 ,
 $\mu_1 - \mu_2$, $\mu_1 - \mu_2$, $\frac{1}{2}(\mu_1 + \mu_2) - \mu_3 \dots$
- ▶ We will construct a confidence interval for a linear combination of these means. We denote the linear combination as

$$L = c_1\mu_1 + c_2\mu_2 + \dots + c_r\mu_r$$

$$\mu_1: c_1 = 1, c_2 = c_3 = \dots = c_r = 0$$

$$\mu_1 - \mu_2: c_1 = 1, c_2 = -1, 0 \text{ for others.}$$

Confidence interval for linear combination of means

$$y_{ij} \sim N(\mu_i, \sigma^2).$$

$\hat{\mu}_i$ ↑

- ▶ Since the estimate for μ_i is $\bar{y}_{i.}$, the estimate of L is

$$\hat{L} = c_1 \bar{y}_{1.} + c_2 \bar{y}_{2.} + \cdots + c_r \bar{y}_{r.}$$

- ▶ Under the one-way normal model, $\bar{y}_{i.} \sim N(\mu_i, \sigma^2/n_i)$.
So

$$\hat{L} \sim N\left(c_1 \mu_1 + c_2 \mu_2 + \cdots + c_r \mu_r, \sigma^2 \left(\frac{c_1^2}{n_1} + \frac{c_2^2}{n_2} + \cdots + \frac{c_r^2}{n_r}\right)\right)$$

Confidence interval for linear combination of means

- Thus

$$\frac{\hat{L} - L}{\sigma \sqrt{\frac{c_1^2}{n_1} + \frac{c_2^2}{n_2} + \cdots + \frac{c_r^2}{n_r}}} \sim N(0, 1)$$

- Replacing the unknown σ with the pooled sample standard deviation, then

$$\frac{\hat{L} - L}{s_P \sqrt{\frac{c_1^2}{n_1} + \frac{c_2^2}{n_2} + \cdots + \frac{c_r^2}{n_r}}} \sim t_{n-r}$$

- Therefore a two-sided $1 - \alpha$ confidence interval is

$$\hat{L} \pm t_{n-r, 1-\alpha/2} s_P \sqrt{\frac{c_1^2}{n_1} + \frac{c_2^2}{n_2} + \cdots + \frac{c_r^2}{n_r}}$$

The one-sided confidence intervals are analogous.

$$\hat{L} \pm t_{n-r, 1-\alpha} se(\hat{L})$$

Inference

Confidence interval
for linear
combination of
means

Example: railroad rails

Different from one-sample or two-sample inference!

Construct the following confidence intervals with the JMP output:

always use S_p and t_{n-r} for one-way model.

1. 95% two-sided confidence interval for μ_1
2. 95% two-sided confidence interval for $\mu_1 - \mu_2$
3. 95% lower confidence bound for $\mu_3 - \mu_5$
4. 90% two-sided confidence interval for $\frac{1}{2}(\mu_1 + \mu_2) - \mu_3$

Least Squares Means Table *gi.*

Level	Least Sq Mean	Std Error	Mean
1	54.000000	2.3213980	54.0000

Example: railroad rails

Table B.4

1. $t_{n-r, 1-\alpha/2} = t_{18-6, 1-0.05/2} = t_{12, 0.975} = 2.179$. So

$$\begin{aligned} \hat{\mu}_1 & \quad \bar{y}_1 \pm t_{12, 0.975} SP \sqrt{\frac{1^2}{3}} \\ & = 54.000 \pm 2.179(4.021) \sqrt{1/3} \\ & = 54 \pm 5.059 \\ & = (48.941, 59.059) \end{aligned}$$

$C_1 = 1, C_2 = \dots C_6 = 0$
 $n_1 = 3$

We are 95% confident that the mean mechanical wave travel time for Rail 1 is any number between 48.941 and 59.059 nanoseconds.

2. $t_{n-r, 1-\alpha/2} = t_{18-6, 1-0.05/2} = t_{12, 0.975} = 2.179$. So

$\hat{\mu}_1 - \hat{\mu}_2$

$$\bar{y}_1 - \bar{y}_2 \pm t_{12, 0.975} \sqrt{\frac{1^2}{3} + \frac{(-1)^2}{3}}$$

$C_1 = 1, C_2 = -1$
 $C_3 = \dots = C_6 = 0$
 $n_1 = n_2 = 3$

$$= (54.000 - 31.667) \pm 2.179(4.021) \sqrt{2/3}$$

$$= 22.333 \pm 7.154$$

$$= (15.179, 29.487)$$

3. $t_{n-r, 1-\alpha} = t_{18-6, 1-0.05} = t_{12, 0.95} = 1.782$. So the lower 95% confidence bound is

$$\begin{aligned} & \hat{\mu}_3 - \hat{\mu}_5 - \underbrace{t_{12, 0.95}}_{1.782} \underbrace{SP}_{4.021} \sqrt{\frac{1^2}{3} + \frac{(-1)^2}{3}} \\ &= (84.667 - 50.000) \pm 1.782(4.021) \sqrt{2/3} \\ &= 34.667 - 5.851 \\ &= \underline{28.816} \end{aligned}$$

Handwritten notes:
 $C_3 = 1, C_5 = -1$
 0 for the other.
 $n_3 = n_5 = 3$.

residuals

Inference

Confidence interval
for linear
combination of
means

We are 95% confident that the mean mechanical wave travel time for Rail 3 is longer than that of Rail 5 by at least 28.816 nanoseconds.

Example: railroad rails $\frac{1}{2}(\mu_1 + \mu_2) - \mu_3$ $c_1 = \frac{1}{2}, c_2 = \frac{1}{2}$
 $= \frac{1}{2}\mu_1 + \frac{1}{2}\mu_2 - \mu_3 \Rightarrow c_3 = -1$

4. $t_{n-r, 1-\alpha/2} = t_{18-6, 1-0.1/2} = t_{12, 0.95} = 1.782$. So $\frac{(\frac{1}{2} + \frac{1}{2} + 1)}{3} = \frac{1}{2}$

$$\begin{aligned} & \frac{1}{2}\bar{y}_1 + \frac{1}{2}\bar{y}_2 - \bar{y}_3 \pm t_{12, 0.95} SP \sqrt{\frac{(1/2)^2}{3} + \frac{(1/2)^2}{3} + \frac{(-1)^2}{3}} \\ &= \left(\frac{1}{2} 54.000 + \frac{1}{2} 31.667 - 84.667 \right) \pm 1.782 (4.021) \sqrt{1/2} \\ &= -41.834 \pm 5.067 \\ &= (-46.901, -36.767) \end{aligned}$$

We are 90% confident that the average of the mean mechanical wave travel times for Rail 1 and Rail 2 is shorter than the mean mechanical wave travel time of Rail 3 by any number between 46.901 and 36.767 nanoseconds.
